PeopleDesk

HR Policy Knowledge Assistant

RAG Chatbot — Project Report

Workflow implementation using n8n and Ollama

Project overview

PeopleDesk adapts the supplied CyberON cybersecurity RAG chatbot reference into an HR-domain knowledge assistant. The intended chatbot retrieves relevant passages from HR policy documents and uses them to answer employee questions.

Report note

This report follows the reference PDF's structure: document insertion, workflow architecture, chatbot interface, sample user query, response, technical query, and memory follow-up. Screenshot spaces are placeholders for replacement with the project's own HR workflow and test results.

1. Inserting HR Documents into the Simple Vector Store Database

The knowledge base should contain HR documents such as leave policy, attendance policy, onboarding guidelines, and employee benefits information. These may be approved public documents or clearly labelled fictional documents created for the assignment.

Sample document	Content to include
01_Leave_Policy.pdf	Leave categories, eligibility, application process, notice requirements, and approval steps.
02_Attendance_Policy.pdf	Working hours, attendance recording, late arrivals, and attendance regularization.
03_Onboarding_Guide.pdf	Joining formalities, documents required, induction, and employee setup.
04_Benefits_Policy.pdf	Employee benefits, eligibility criteria, claims, and conditions.

The document-ingestion path should load the files, extract text, generate embeddings, and insert the resulting document chunks into the Simple Vector Store. The data loader and embedding connections must be checked in n8n to confirm that indexing is actually performed.

Figure 1. HR document insertion workflow

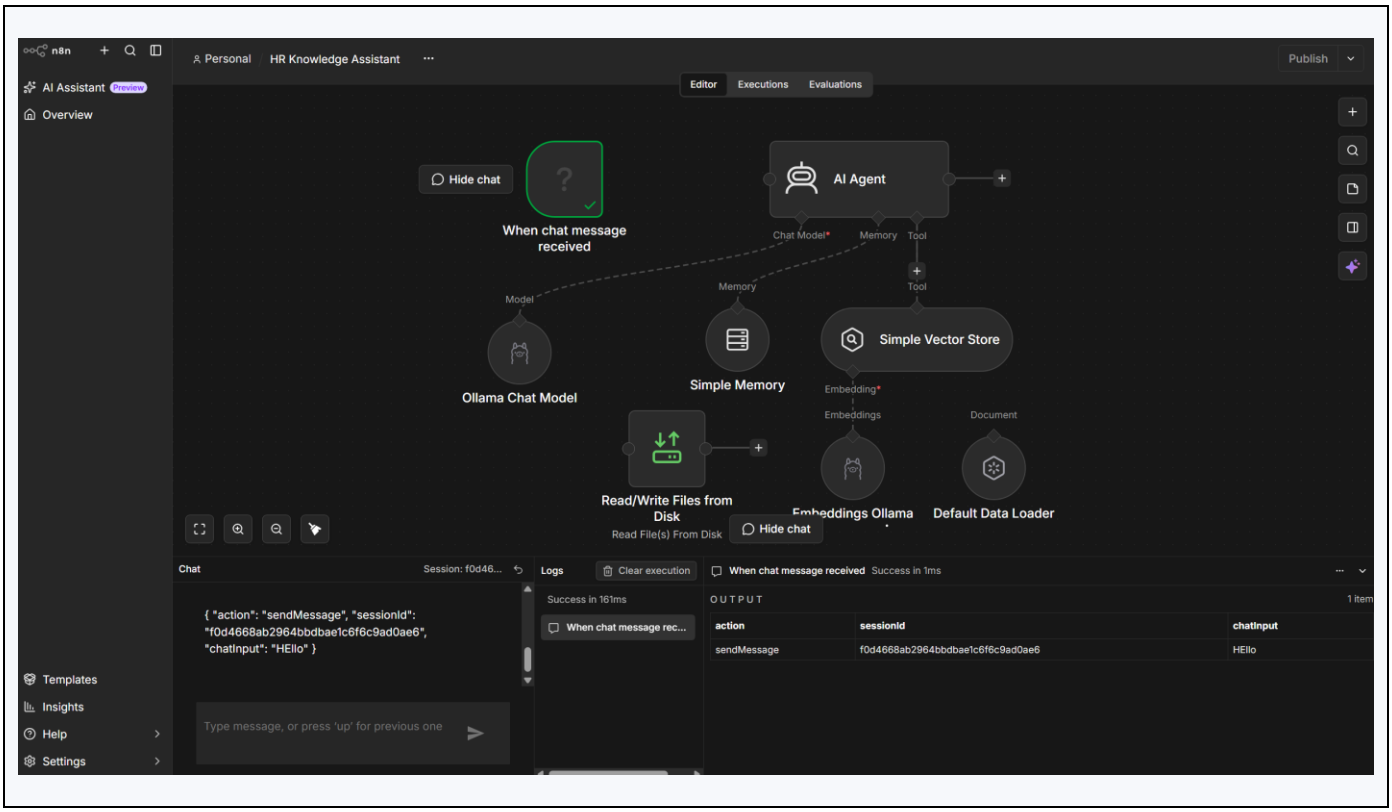

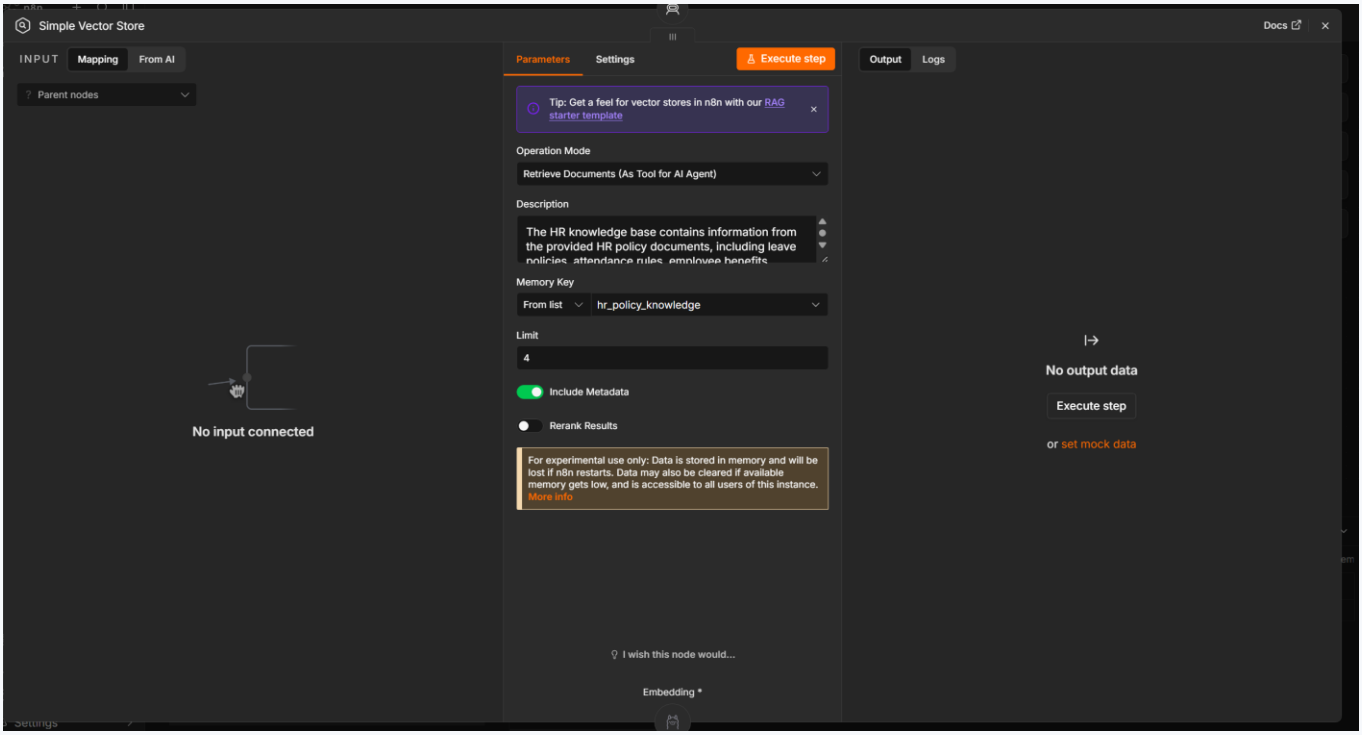

Figure 2. Vector store insertion settings

2. Workflow Architecture

The planned workflow follows the reference design: a chat trigger sends the employee's message to an AI Agent, which can query the Simple Vector Store as a retrieval tool. The agent uses an Ollama chat model to formulate an answer and Simple Memory to support follow-up questions.

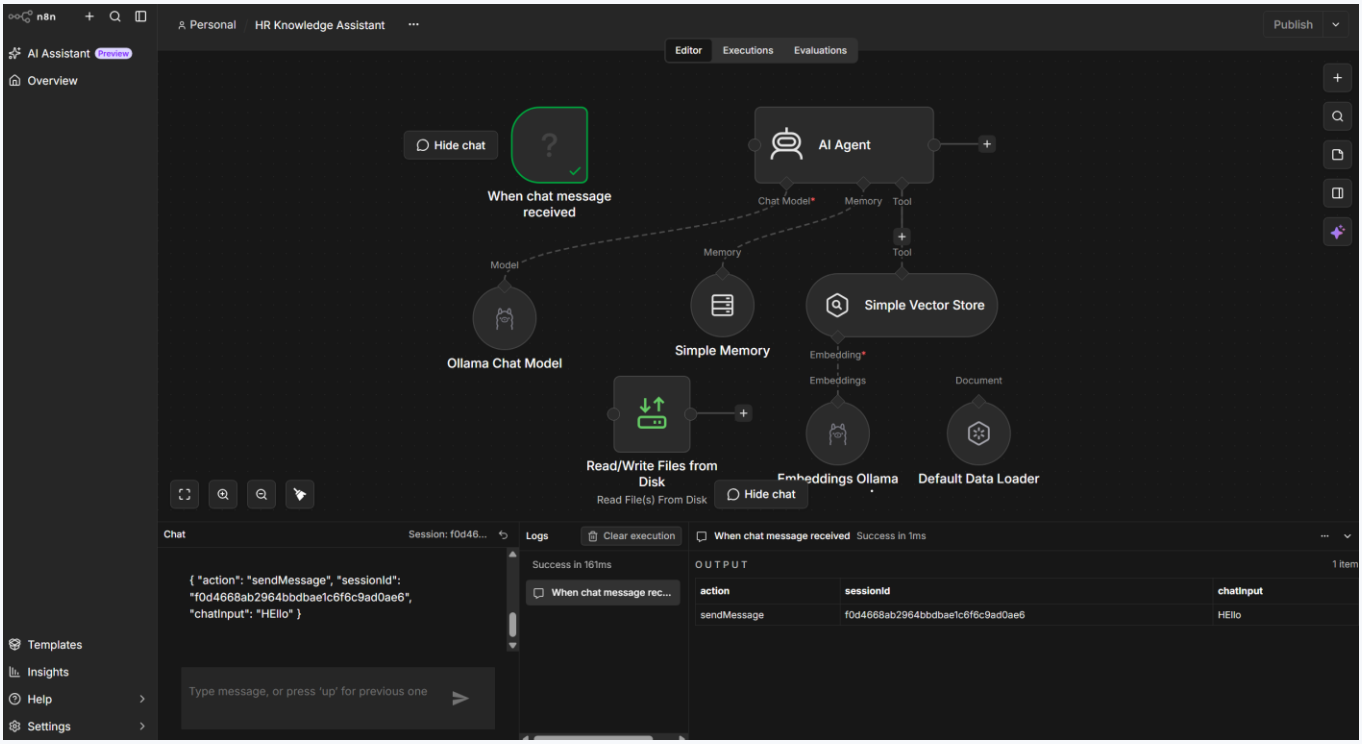

```
When chat message received  →  HR Policy Assistant
                                  ├─ Chat Model: Ollama
                                  ├─ Memory: Simple Memory
                                  └─ Tool: Simple Vector Store (HR policy retrieval)

Document ingestion: HR files → Default Data Loader → Ollama Embeddings → Simple Vector Store
```

Node / component	Function
When chat message received	Starts the workflow when an employee submits a question.
HR Policy Assistant (AI Agent)	Understands the question, retrieves supporting content, and prepares the answer.
Ollama Chat Model	Runs the local language model used to generate the response.
Simple Memory	Keeps conversational context for follow-up questions.
Simple Vector Store	Stores document vectors and retrieves relevant HR content.
Ollama Embeddings	Creates vector representations of HR document chunks and queries.
Default Data Loader	Loads documents and metadata for indexing.
Read/Write Files from Disk	May be used for file handling if configured and connected to the ingestion path.

Implementation note: the supplied reference states that its chatbot worked while the Groq model briefly reached its token limit. PeopleDesk uses a local Ollama model as the intended alternative; successful connectivity and execution must be verified before claiming the HR chatbot is fully functional.

Figure 3. PeopleDesk workflow architecture

3. Chatbot Interface

The chat interface is the employee-facing entry point. It should use HR-focused wording so users understand the assistant's scope.

UI element	Suggested text
Chatbot title	PeopleDesk — HR Policy Assistant
Subtitle	Ask questions about HR policies and employee procedures.
Initial greeting	Hi! I'm PeopleDesk, your HR Policy Assistant. Ask me about leave, attendance, onboarding, benefits, or workplace policies.
Input placeholder	Ask an HR policy question...

The response should be concise, grounded in retrieved policy content, and include a source document name when the retrieval metadata makes it available. If the policy does not state an answer, the assistant should say so and recommend checking with HR.

```
Illustrative response format:
“According to the uploaded [policy document], [summarize only the rule supported by the retrieved passage].
The document also states [relevant condition, if present]. Please contact HR if you need confirmation for an
exception.”
```

This is a response template, not a claim about the contents of a particular HR policy. Replace it with the actual output captured during testing..

4. Model, Embeddings, and Memory Configuration

Component	Intended configuration
Ollama chat model	llama3.2:latest, if selected and available in n8n.
Ollama endpoint	http://127.0.0.1:11434 when n8n and Ollama run directly on the same Windows host; other environments may require a different host address.
Embedding model	nomic-embed-text:latest.
Simple Memory	Use the chat session identifier so follow-up turns share context.

A previous attempt produced ECONNREFUSED ::1:11434. For a direct Windows setup, test the IPv4 loopback URL above and verify that Ollama is running. If n8n is containerized, localhost refers to the container and the correct host address must be configured.

Figure 10. Ollama chat model and embedding configuration

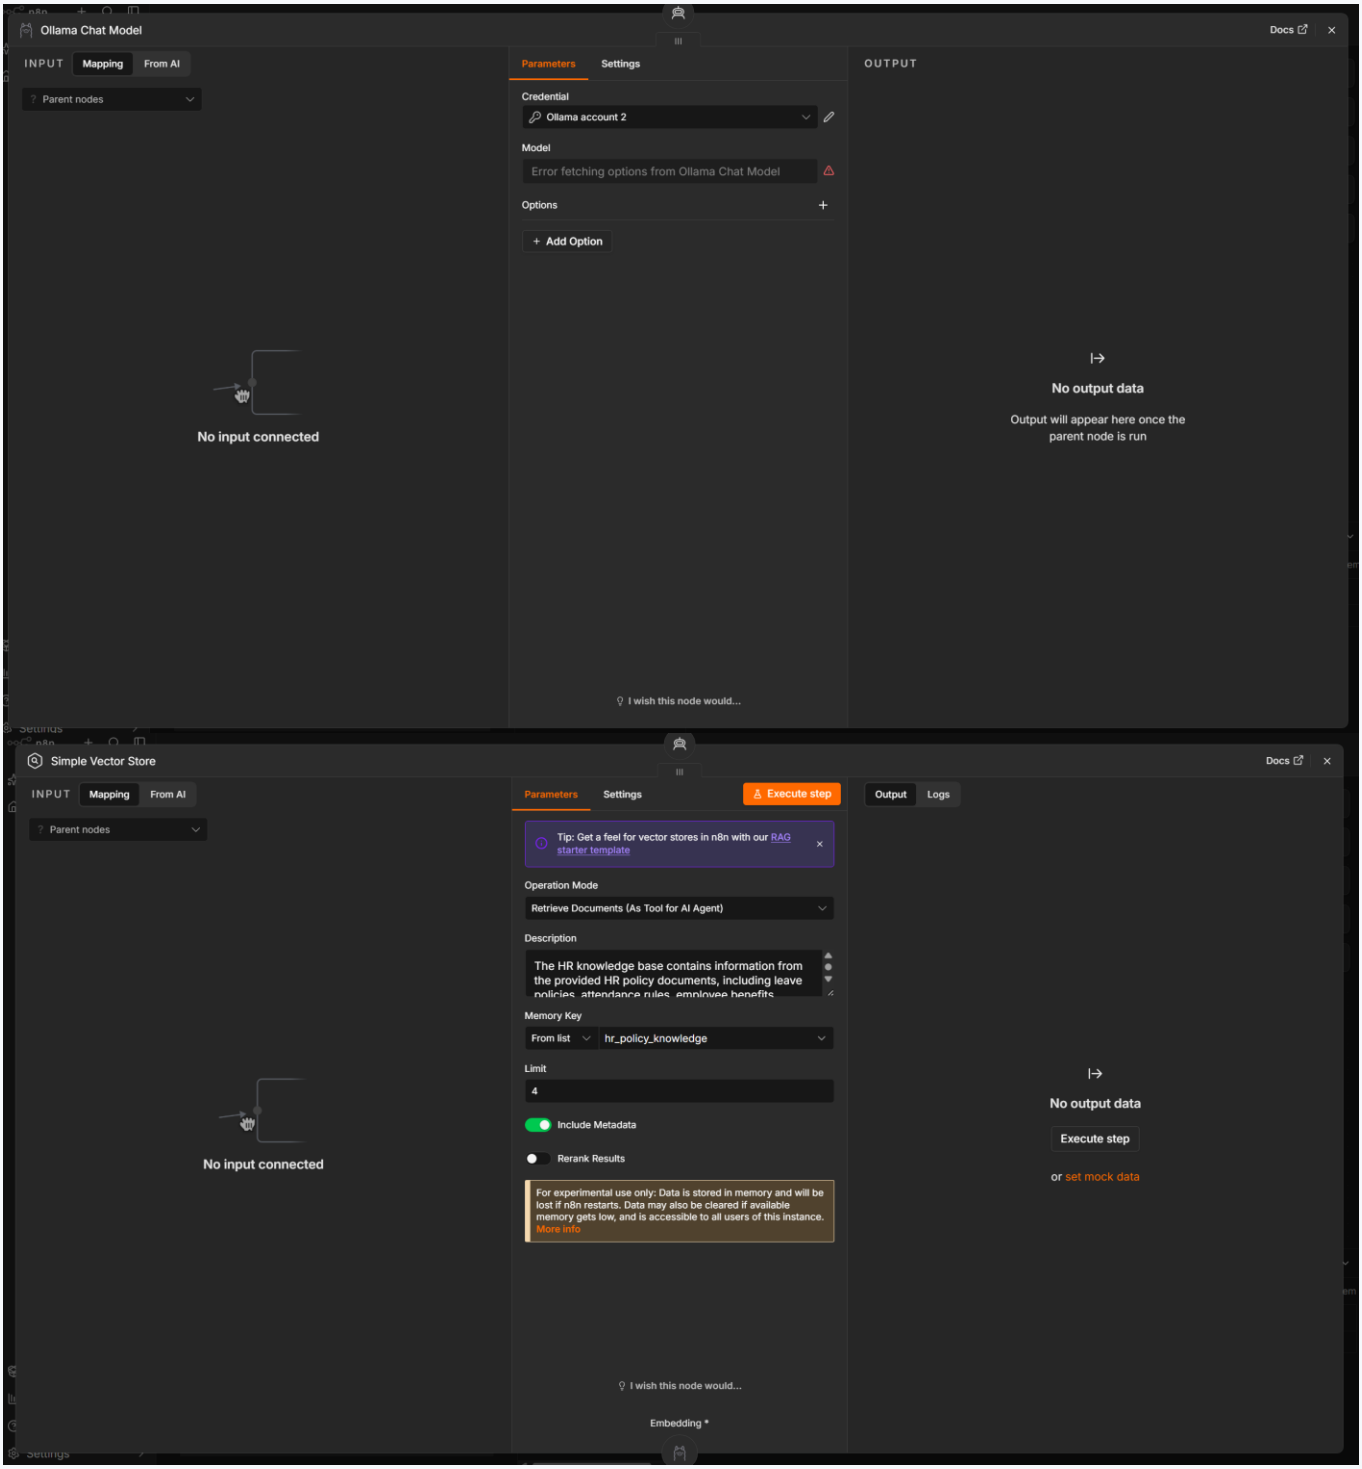

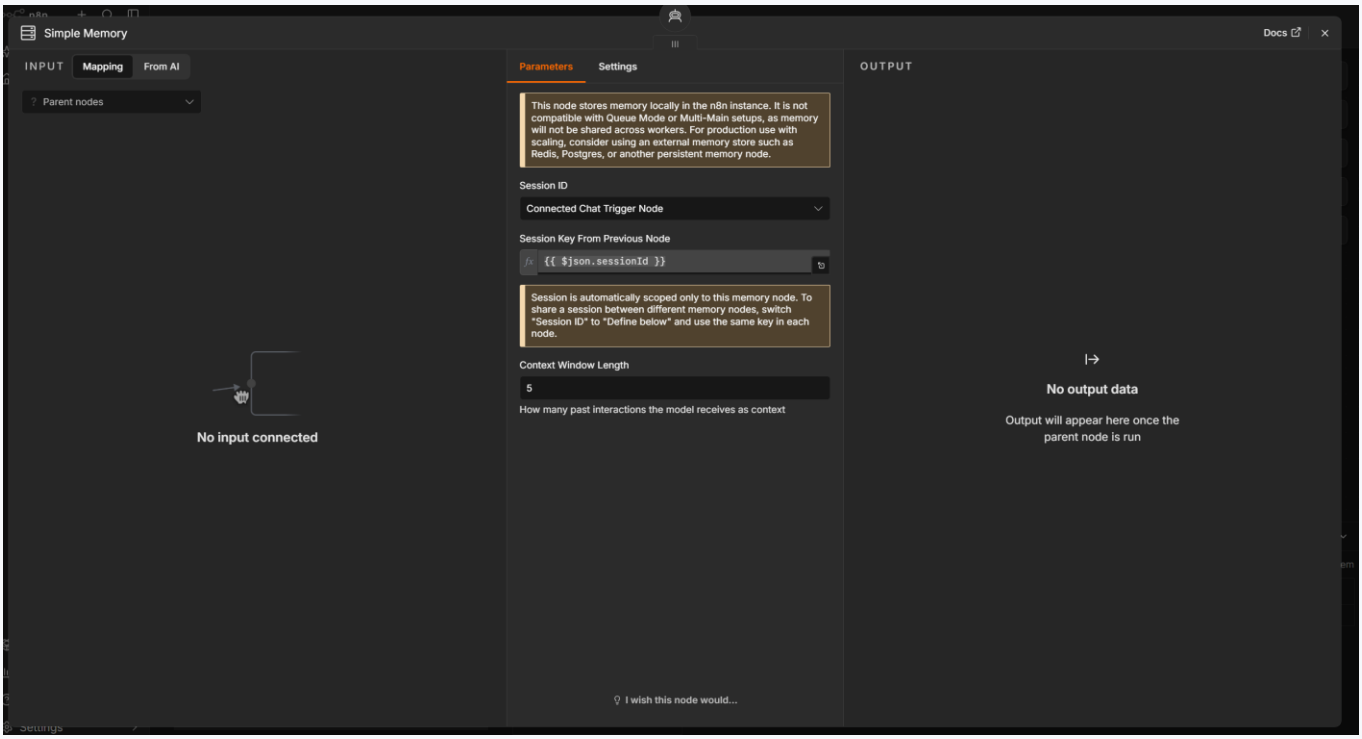

Figure 11. Simple Memory configuration

10. Testing and Implementation Status

Test case	What it verifies	Status
HR document indexing	Documents are loaded and stored under the HR key.	Pending validation
Simple policy query	Relevant policy text is retrieved and summarized.	Pending validation
Detailed procedural query	Multiple relevant details are retrieved without invention.	Pending validation
Follow-up question	Chat session memory resolves a contextual follow-up.	Pending validation
Missing information	Assistant acknowledges when the knowledge base does not support an answer.	Pending validation
End-to-end workflow	Chat trigger, model, retrieval, and response complete without errors.	Pending validation

The supplied CyberON reference shows document insertion into the Simple Vector Store (page 1), the workflow canvas and a note about a temporary Groq token-limit issue (page 2), the chat interface and first query (page 3), a response and more technical query (page 4), and a memory follow-up (page 5). This report follows that same demonstration sequence for PeopleDesk.

Conclusion

PeopleDesk adapts the reference RAG chatbot structure to HR policy assistance. The planned demonstration should show HR document insertion, the full workflow architecture, the chat interface, a simple query and response, a detailed query, and a contextual follow-up. The report is a draft until the HR documents are indexed and each test is captured from the working n8n workflow.
